

Package ‘robustX’

February 2, 2017

Type Package

Title 'eXtra' / 'eXperimental' Functionality for Robust Statistics

Version 1.2-2

Date 2017-02-02

Author Werner Stahel, Martin Maechler and potentially others

Maintainer Martin Maechler <maechler@stat.math.ethz.ch>

Description Robustness -- 'eXperimental', 'eXtraneous', or 'eXtraordinary'
Functionality for Robust Statistics. In other words, methods which are not
yet well established, often related to methods in package 'robustbase'.

Imports grDevices, graphics, stats, utils, robustbase (>= 0.92-3)

Suggests MASS, lattice

Enhances ICS

License GPL (>= 2)

Encoding UTF-8

NeedsCompilation no

Repository CRAN

--------------	-----------

Description

The package **robustX** aims to be a collection of R functionality for robust statistics of methods and ideas that are considered as proposals, experimental, for experiences or just too much specialized to be part of the “Robust Basics” package **robustbase**.

Details

Package: robustX
Date: 2008-12-17, was the first, R-forge only
Version: 1.2-0
Depends: robustbase
License: GPL (>= 2)

Index:

Qrot Rotation Matrix to Specific Direction
rbwheel Multivariate Barrow Wheel Distribution
 Random Vectors
L1median Compute the Multivariate L1-Median
BACON BACON for Regression or Multivariate Covariance Estimation
mvBACON BACON: Blocked Adaptive
Computationally-Efficient Outlier Nominators

Author(s)

Werner Stahel, Martin Maechler and potentially others

Maintainer: Martin Maechler

Examples

```
pairs( rbwheel(100, 4) )
```

Description

BACON, short for ‘Blocked Adaptive Computationally-Efficient Outlier Nominators’, is a somewhat robust algorithm (set), with an implementation for regression or multivariate covariance estimation.

BACON() applies the multivariate (covariance estimation) algorithm, using `mvBACON(x)` in any case, and when `y` is not NULL adds a regression iteration phase, using the auxiliary `.lmBACON()` function.

Usage

```
BACON(x, y = NULL, intercept = TRUE,
      m = min(collect * p, n * 0.5),
      init.sel = c("Mahalanobis", "dUniMedian", "random", "manual"),
      man.sel, init.fraction = 0, collect = 4,
      alpha = 0.95, maxsteps = 100, verbose = TRUE)
```

```
## *Auxiliary* function:
```

```
.lmBACON(x, y, intercept = TRUE,
         init.dis, init.fraction = 0, collect = 4,
         alpha = 0.95, maxsteps = 100, verbose = TRUE)
```

Arguments

<code>x</code>	a multivariate matrix of dimension [n x p] considered as containing no missing values.
<code>y</code>	the response (n vector) in the case of regression, or NULL for the multivariate case.
<code>intercept</code>	logical indicating if an intercept has to be used for the regression.
<code>m</code>	integer in 1:n specifying the size of the initial basic subset; used only when <code>init.sel</code> is not "manual"; see <code>mvBACON</code> .
<code>init.sel</code>	character string, specifying the initial selection mode; see <code>mvBACON</code> .
<code>man.sel</code>	only when <code>init.sel == "manual"</code> , the indices of observations determining the initial basic subset (and <code>m <- length(man.sel)</code>).
<code>init.dis</code>	the distances of the x matrix used for the initial subset determined by <code>mvBACON</code> .
<code>init.fraction</code>	if this parameter is > 0 then the tedious steps of selecting the initial subset are skipped and an initial subset of size <code>n * init.fraction</code> is chosen (with smallest dis)
<code>collect</code>	numeric factor chosen by the user to define the size of the initial subset (<code>p * collect</code>)
<code>alpha</code>	significance level.
<code>maxsteps</code>	the maximal number of iteration steps (to prevent infinite loops)
<code>verbose</code>	logical indicating if messages are printed which trace progress of the algorithm.

Details

init.sel: the initial selection mode; implemented modes are: "Mah" -> based on Mahalanobis distance (default) "dis" -> based on the distances from the medians "ran" -> based on a random selection "man" -> based on manual selection in this case the vector 'man.sel' which contains the indices of the selected observations must be given. "Mah" and "dis" are proposed by Hadi while "ran" and "man" were implemented in order to study the behaviour of BACON.

Value

basically a `list` with components

subset the observation indices (in 1:n) denoting the subset of “good” observations.
tis

Author(s)

Ueli Oetliker, Swiss Federal Statistical Office, for S-plus 5.1; 25.05.2001; modified six times till 17.6.2001.

Port to R, testing etc, by Martin Maechler.

[mvBACON](#), the multivariate version of the BACON algorithm.

Examples

```
data(starsCYG, package = "robustbase")
## Plot simple data and fitted lines
plot(starsCYG)
  lmST <- lm(log.light ~ log.Te, data = starsCYG)
(B.ST <- with(starsCYG, BACON(x = log.Te, y = log.light)))
require(robustbase)
(RlmST <- lmrob(log.light ~ log.Te, data = starsCYG))
abline(lmST, col = "red")
abline(RlmST, col = "blue")
```

covNNC

*Robust Covariance Estimation via Nearest Neighbor Cleaning***Description**

covNNC() estimates robust covariance/dispersion matrices by the nearest neighbor variance estimation (NNVE) or (rather) “Nearest Neighbor Cleaning” (NNC) method of Wang and Raftery (2002, *JASA*).

Usage

```
covNNC(X, k = min(12, n - 1), pnoise = 0.05, emconv = 0.001,
        bound = 1.5, extension = TRUE, devsm = 0.01)
```

Arguments

X	matrix in which each row represents an observation or point and each column represents a variable.
k	desired number of nearest neighbors (default is 12)
pnoise	percent of added noise
emconv	convergence tolerance for EM
bound	value used to identify surges in variance caused by outliers wrongly included as signal points (bound = 1.5 means a 50 percent increase)
extension	whether or not to continue after reaching the last chi-square distance. The default is to continue, which is indicated by setting extension = TRUE.
devsm	when extension = TRUE, the algorithm stops if the relative difference in variance is less than devsm. (default is 0.01)

Value

A list with components

cov	covariance matrix
mu	mean vector
postprob	posterior probability
classification	classification (0=noise otherwise 1) obtained by rounding postprob
innc	list of initial nearest neighbor cleaning results (components are the covariance, mean, posterior probability and classification)

Note

Terms of use: GPL version 2 or newer.

MM: Even though covNNC() is backed by a serious scientific publication, I cannot recommend its use at all.

Author(s)

Naisyin Wang <nwang@stat.tamu.edu> and Adrian Raftery <raftery@stat.washington.edu> with contributions from Chris Fraley <fraley@stat.washington.edu>.

covNNC(), then named cov.nnve(), used to be (the only function) in CRAN package **covRobust** (2003), which was archived in 2012.

Martin Maechler allowed `ncol(X) == 1`, sped up the original code, by reducing the amount of scaling; further, the accuracy was increased (using internal `q.ddk()`). The original version is available, unexported as `robustX:::covNNC1`.

covNNC(iris[-5])

data(hbk, package="robustbase")
hbk.x <- data.matrix(hbk[, 1:3])
covNNC(hbk.x)
```

L1median

Compute the Multivariate L1-Median

Description

Compute the multivariate L_1 -median m , i.e., the minimizer of

$$\sum_{i=1}^n \|x_i - m\|,$$

where $\|u\| = \sqrt{\sum_{j=1}^p u_j^2}$.

As a convex problem, there's always a global minimizer, computable not by a closed formula but rather an iterative search. As the (partial) first derivatives of the objective function is undefined at the data points, the minimization is not entirely trivial.

Usage

```
L1median(X, m.init = colMedians(X), weights = NULL,
method = c("nlm", "HoCrJo", "VardiZhang", optimMethods, nlmInbMethods),
pscale = apply(abs(centr(X, m.init)), 2, mean, trim = 0.40),
tol = 1e-08, maxit = 200, trace = FALSE,
zero.tol = 1e-15, ...)
```

Arguments

<code>X</code>	numeric <i>matrix</i> of dimension $n \times p$, say.
<code>m.init</code>	starting value for m ; typically and by default the coordinatewise median.
<code>weights</code>	optional numeric vector of non-negative weights; currently only implemented for method "VardiZhang".
<code>method</code>	character string specifying the computational method, i.e., the algorithm to be used (can be abbreviated).
<code>pscale</code>	numeric p -vector of positive numbers, the coordinate-wise scale (typical size of δm_j), where m is the problem's solution.
<code>tol</code>	positive number specifying the (relative) convergence tolerance.
<code>maxit</code>	positive integer specifying the maximal number of iterations (before the iterations are stopped prematurely if necessary).
<code>trace</code>	an integer specifying the tracing level of the iterations; 0 does no tracing
<code>zero.tol</code>	for method "VardiZhang", a small positive number specifying the tolerance for determining that the iteration is 'exactly' at a data point (which is a singularity).
<code>...</code>	optional arguments to <code>nlm()</code> or the control (list) arguments of <code>optim()</code> , or <code>nlminb()</code> , respectively.

Details

Currently, we have to refer to the "References" below.

Value

currently the result *depends* strongly on the method used.
 FIXME. This will change considerably.

Author(s)

Martin Maechler. Method "HoCrJo" is mostly based on Kristel Joossens' R function, implementing Hossjer and Croux (1995).

[median](#), [covMcd](#)

CRAN package **pcaPP** added more L1 median methods, re-implementing our R versions in C++, see Fritz et al.(2012) and e.g., [l1median_NLM\(\)](#).

Examples

```
data(stackloss)
L1median(stackloss)
L1median(stackloss, method = "HoCrJo")

## Explore all methods:
m <- eval(formals(L1median)$method); allMeths <- m[m != "Brent"]
L1m <- sapply(allMeths, function(meth) L1median(stackloss, method = meth))
## --> with a warning for L-BFGS-B
str(L1m)
pm <- sapply(L1m, function(.) if(is.numeric(.)) . else .$par)
t(pm) # SANN differs a bit; same objective ?
```

mvBACON

BACON: Blocked Adaptive Computationally-Efficient Outlier Nominators

Description

This function performs an outlier identification algorithm to the data in the x array [n x p] and y vector [n] following the lines described by Hadi et al. for their BACON outlier procedure.

Usage

```
mvBACON(x, collect = 4, m = min(collect * p, n * 0.5), alpha = 0.95,
        init.sel = c("Mahalanobis", "dUniMedian", "random", "manual"),
        man.sel, maxsteps = 100, allowSingular = FALSE, verbose = TRUE)
```

Arguments

x	numeric matrix (of dimension [n x p]), not supposed to contain missing values.
collect	a multiplication factor, when <code>init.sel</code> is not "manual", to define <i>m</i> , the size of the initial basic subset, as <code>m <- min(p * collect, n/2)</code> .
m	integer in 1:n specifying the size of the initial basic subset; used only when <code>init.sel</code> is not "manual".
alpha	significance level for the χ^2 cutoff, used to define the next iterations basic subset.

<code>init.sel</code>	character string, specifying the initial selection mode; implemented modes are: "Mahalanobis" based on Mahalanobis distances (default) "dUniMedian" based on the distances from the univariate medians "random" based on a random selection "manual" based on manual selection; in this case, a vector <code>man.sel</code> containing the indices of the selected observations must be specified. "Mahalanobis" , "dUniMedian" where proposed by Hadi and the other authors in the reference as versions 'V_1' and 'V_2', as well as "manual" , while "random" is provided in order to study the behaviour of BACON.
<code>man.sel</code>	only when <code>init.sel == "manual"</code> , the indices of observations determining the initial basic subset (and <code>m <- length(man.sel)</code>).
<code>maxsteps</code>	maximal number of iteration steps.
<code>allowSingular</code>	logical indicating a solution should be sought also when no matrix of rank p is found.
<code>verbose</code>	logical indicating if messages are printed which trace progress of the algorithm.

Value

a list with components

<code>subset</code>	logical vector of length n where the i -th entry is true iff the i -th observation is part of the final selection.
<code>dis</code>	numeric vector of length n with the (Mahalanobis) distances.
<code>cov</code>	$p \times p$ matrix, the corresponding robust estimate of covariance.

See Also

[covMcd](#) for a high-breakdown (but more computer intensive) method; [BACON](#) for a “generalization”, notably to *regression*.

Examples

```
require(robustbase) # for example data and covMcd():
## simple 2D example :
plot(starsCYG, main = "starsCYG data (n=47)")
B.st <- mvBACON(starsCYG)
points(starsCYG[ ! B.st$subset,], pch = 4, col = 2, cex = 1.5)
```

```

stopifnot(identical(which(!B.st$subset), c(7L,9L,11L,14L,20L,30L,34L)))
## finds the clear outliers (and 3 "borderline")

## 'coleman' from pkg 'robustbase'
coleman.x <- data.matrix(coleman[, 1:6])
Cc <- covMcd (coleman.x) # truly robust
summary(Cc) # -> 6 outliers (1,3,10,12,17,18)
Cb1 <- mvBACON(coleman.x) ##-> subset is all TRUE hmm??
Cb2 <- mvBACON(coleman.x, init.sel = "dUniMedian")
stopifnot(all.equal(Cb1, Cb2))
Cb.r <- lapply(1:20, function(i) { set.seed(i)
                                mvBACON(coleman.x, init.sel="random", verbose=FALSE) })
nm <- names(Cb.r[[1]]); nm <- nm[nm != "steps"]
all(eqC <- sapply(Cb.r[-1], function(CC) all.equal(CC[nm], Cb.r[[1]][nm]))) # TRUE
## --> BACON always breaks down, i.e., does not see the outliers here
## breaks down even when manually starting with all the non-outliers:
Cb.man <- mvBACON(coleman.x, init.sel = "manual",
                  man.sel = setdiff(1:20, c(1,3,10,12,17,18)))
which( ! Cb.man$subset) # the outliers according to mvBACON : _none_

```

Qrot

Rotation Matrix to Specific Direction

Description

Construct the $p \times p$ rotation matrix that rotates the unit vector $(1,0,\dots,0)$, i.e., the x_1 -axis, onto $(1,1,1,\dots,1)/\sqrt{p}$, or more generally to $u/\|u\|$ ($u := \text{unit.image}$).

Usage

```
Qrot(p, transpose = FALSE, unit.image = rep(1, p))
```

Arguments

<code>p</code>	integer; the dimension (of the vectors involved).
<code>transpose</code>	logical indicating if the <i>transposed</i> matrix is to returned.
<code>unit.image</code>	numeric vector of length p onto which the unit vector should be rotated; defaults to “ <i>the diagonal</i> ” $\propto (1, 1, 1, \dots, 1)$.

Details

The `qr` decomposition is used for a Gram-Schmitt basis orthogonalization.

Value

$p \times p$ orthogonal matrix which rotates $(1, 0, \dots, 0)$ onto a vector proportional to `unit.image`.

Author(s)

Martin Maechler

See Also[qr](#), matrix (and vector) multiplication, `%%`.**Examples**

```

Q <- Qrot(6)
zapsmall(crossprod(Q)) # 6 x 6 unity <==> Q'Q = I <==> Q orthogonal

if(require("MASS")) {
  Qt <- Qrot(6, transpose = TRUE)
  stopifnot(all.equal(Qt, t(Q)))
  fractions(Qt ^2) # --> 1/6 1/30 etc, in an almost lower-triagonal matrix
}

```

rbwheel

*Multivariate Barrow Wheel Distribution Random Vectors***Description**

Generate p -dimensional random vectors according to Stahel's Barrow Wheel Distribution.

Usage

```

rbwheel(n, p, frac = 1/p, sig1 = 0.05, sig2 = 1/10,
        rGood = rnorm,
        rOut = function(n) sqrt(rchisq(n, p - 1)) * sign(runif(n, -1, 1)),
        U1 = rep(1, p),
        scaleAfter = TRUE, scaleBefore = FALSE, spherize = FALSE,
        fullResult = FALSE)

```

Arguments

<code>n</code>	integer, specifying the sample size.
<code>p</code>	integer, specifying the dimension (aka number of variables).
<code>frac</code>	numeric, the proportion of outliers. The default, $1/p$, corresponds to the (asymptotic) breakdown point of M-estimators.
<code>sig1</code>	thickness of the "wheel", ($= \sigma(\text{good}[, 1])$), a non-negative numeric.
<code>sig2</code>	thickness of the "axis" (compared to 1).
<code>rGood</code>	function; the generator for "good" observations.
<code>rOut</code>	function, generating the outlier observations.
<code>U1</code>	p -vector to which $(1, 0, \dots, 0)$ is rotated.

scaleAfter	logical indicating if the matrix is re-scaled <i>after</i> rotation (via <code>scale()</code>). Default TRUE; note that this used to be false by default in the first public version.
scaleBefore	logical indicating if the matrix is re-scaled before rotation (via <code>scale()</code>).
spherize	logical indicating if the matrix is to be “spherized”, i.e., rotated and scaled to have empirical covariance I_p . This means that the principal components are used (before rotation).
fullResult	logical indicating if in addition to the $n \times p$ matrix, some intermediate quantities are returned as well.

Details

....

Value

By default (when `fullResult` is FALSE), an $n \times p$ matrix of n sample vectors of the p dimensional barrow wheel distribution, with an attribute, `n1` specifying the exact number of “good” observations, $n1 \approx (1 - f) \cdot n$, $f = \text{frac}$.

If `fullResult` is TRUE, a list with components

X	the $n \times p$ matrix of above, $X = X0 \%*\% A$, where $A \leftarrow \text{Qrot}(p, u = U1)$, and $X0$ is the corresponding matrix before rotation, see below.
X0
A	the $p \times p$ rotation matrix, see above.
n1	the number of “good” observations, see above.
n2	the number of “outlying” observations, $n2 = n - n1$.

Author(s)

Examples

```
set.seed(17)
rX8 <- rbwheel(1000,8, fullResult = TRUE, scaleAfter=FALSE)
with(rX8, stopifnot(all.equal(X, X0 %%*% A, tol = 1e-15),
  all.equal(X0, X %%*% t(A), tol = 1e-15)))
##--> here, don't need to keep X0 (nor A, since that is Qrot(p))

## for n = 100, you don't see "it", but may guess .. :
n <- 100
pairs(r <- rbwheel(n,6))
```

```

n1 <- attr(r,"n1") ; pairs(r, col=1+((1:n) > n1))

## for n = 500, you *do* see it :
n <- 500
pairs(r <- rbwheel(n,6))
## show explicitly
n1 <- attr(r,"n1") ; pairs(r, col=1+((1:n) > n1))

## but increasing sig2 does help:
pairs(r <- rbwheel(n,6, sig2 = .2))

## show explicitly
n1 <- attr(r,"n1") ; pairs(r, col=1+((1:n) > n1))

set.seed(12)
pairs(X <- rbwheel(n, 7, spherize=TRUE))
colSums(X) # already centered

if(require("ICS")) {
  # ICS: Compare M-estimate [Max.Lik. of t_{df = 2}] with high-breakdown :
  stopifnot(require("MASS"))
  X.paM <- ics(X, S1 = cov, S2 = function(.) cov.trob(., nu=2)$cov, stdKurt = FALSE)
  X.paM.<- ics(X, S1 = cov, S2 = function(.) tM(., df=2)$V, stdKurt = FALSE)
  X.paR <- ics(X, S1 = cov, S2 = function(.) covMcd(.)$cov, stdKurt = FALSE)
  plot(X.paM) # not at all clear
  plot(X.paM.)# ditto
  plot(X.paR)# very clear
}
## Similar such experiments ---> demo(rbwheel_d) and demo(rbwheel_ics)
##                               -----

```

reclas

Recursive Robust Median-like Location and Scale

Description

Calculate an estimate of location, asymptotically equivalent to the median, and an estimate of scale equal to the **MEAN** absolute deviation. Both done recursively.

Usage

```

reclas(y, b = 0.2, mfn = function(n) 0.1 * n^(-0.25),
       nstart = 30, m0 = median(y0),
       scon=NULL, updateScale = is.null(scon))

```

Arguments

y	numeric vector of i.i.d. data whose location and scale parameters are to be estimated.
b	numeric tuning parameter (default value equal to that used by Holst, 1987).
mf _n	a function of the index of the data which must be positive and tend to 0 as the index tends to infinity. The default function is that used by Holst, 1987.
nstart	number of starting values: Starting values for the algorithm are formed from the first nstart values of y. The default value is that used in Cameron and Turner, 1993.
m ₀	value for the initial approximate median; by default, the median of the first nstart observations.
scon	value for the scale parameter s, a function or NULL. When NULL, as by default, the scale is initialized to the mean of the absolute differences between the first nstart y values and m ₀ . If scon is a function, the initial scale is set to scon(y ₀ , m ₀), where y ₀ is the vector of the first nstart y values. Note that scon also determines the default for updateScale.
updateScale	a logical indicating if the scale, initialized from scon should be updated in each iteration. Otherwise, the the scale is held constant throughout and the algorithm becomes equivalent to the algorithm of Holst.

Value

An S3 “object” of **class** “reclas”; simply a list with entries

locn	the successive recursive estimates of location. The first nstart - 1 of these are NA.
scale	the successive recursive estimates of scale if updateScale is true; otherwise the constant value used for the scale.
updateScale	the same as the function argument.
call	the function call, i.e., match.call .

There is a **plot** method for “reclas”, see the examples.

Author(s)

<r.turner@auckland.ac.nz> <http://www.stat.auckland.ac.nz/~rolf>

Extensions by Martin Maechler (scon as function; updateScale, plot()).

- Holst, U. (1987). Recursive estimators of location. *Commun. Statist. — Theory Meth.* **16** (8) 2201–2226.

Examples

```
set.seed(42)
y <- rt(10000, df = 1.5) # not quite Gaussian ...
z1 <- reclas(y)
z3 <- reclas(y, scon= 1 ) # correct fixed scale
z4 <- reclas(y, scon= 100) # wrong fixed scale
z2 <- reclas(y, # a more robust initial scale:
             scon = function(y0, m0) robustbase::Qn(y0 - m0),
             updateScale = TRUE) # still updated

## Visualizing -- using the plot() method for "reclas":
M <- median(y) ; y1 <- c(-1,1)* 0.5
OP <- par(mfrow=c(2,2), mar=.1+c(3,3,1,1), mgp=c(1.5, .6, 0))
plot(z1, M=M, ylim=y1)
plot(z2, M=M, ylim=y1)
plot(z3, M=M, ylim=y1)
plot(z4, M=M, ylim=y1)
par(OP)
```
